Appendix — PoC Scoping Checklist & Assumptions

1. Executive Summary

Atlas Paints & Tools — a family-owned Lebanese paint manufacturer and hardware/power-tools wholesaler — loses revenue and ties up working capital because procurement is **reactive**. Hardware imports are ordered only after a product (SKU) hits zero, triggering stockouts that routinely last **2+ months** (the supplier lead time). In parallel, slow-moving items accumulate as deadstock because reorder points have never been formalised in the ERP.

This proposal recommends **Inventory Reorder Intelligence** — a weekly reorder recommendation system that turns Atlas's 10+ years of ERP data into proactive procurement decisions. It was selected from the 2nd-deliverable roadmap as the **highest combined impact and feasibility initiative** and the top priority of Phase 2. The proof-of-concept accompanying this proposal demonstrates the full flow end-to-end on synthetic ERP data and validates that the approach works entirely on Atlas's own server — no cloud, no

new infrastructure, no budget ask beyond the consultant's time.

Expected value (order of magnitude, 12 months post-launch):

Lever	Current state	Target with this initiative
Stockout duration on import SKUs	~2 months (entire lead time)	<2 weeks on >80% of events
Deadstock tied up in slow-movers	not currently tracked on a dashboard; estimated ~20–30% from GM discovery — can be measured directly from the ERP's on-hand and sales history	reduce by 30–50% in year 1
Procurement decisions per month	reactive, discovered via stockout	1 review cycle / week, proactive
Inventory working-capital visibility	general ledger only — no product-level coverage, deadstock, or forward-forecast view	weekly dashboard

These figures are illustrative ranges, not commitments. The PoC demonstrates the mechanism; year-1 gains depend on execution and on completing the Phase 0 inventory-accuracy prerequisite.

What's in scope for this initiative: Automated reorder recommendations for roughly 200–500 actively traded products (SKUs) across paint and hardware, with weekly review, human sign-off, a plain-language weekly briefing that triages the week, and a local dashboard for the General Manager (GM) and procurement. The remaining products in the catalogue are raw materials, packaging, or discontinued items and don't need this treatment.

What's out of scope (explicitly): Automatic PO placement with suppliers, multi-location balancing, and production scheduling (that is Phase 3, Use Case A). Advanced AI forecasting techniques are deliberately held back for a later phase if the baseline underperforms on specific product segments.

2. Use Case Scope & Justification

Why this use case

From the 2nd-deliverable prioritization matrix, Use Case B — Inventory Reorder Intelligence scored **3.8 on impact** and **3.8 on feasibility**, placing it in the "Priority Initiative" quadrant and making it the single best impact-per-effort candidate in the entire portfolio.

#	Use Case	Impact	Feasibility	Quadrant
A	Production Planning & Cost Optimization	3.8	3.0	Strategic Bet

#	Use Case	Impact	Feasibility	Quadrant
B	Inventory Reorder Intelligence	3.8	3.8	Priority Initiative
C	Customer Profitability Analysis	2.4	4.8	Quick Win
D	Pricing Optimization	2.6	4.6	Quick Win
E	Sales Forecasting	2.6	3.8	Quick Win

C and D (the two Quick Wins that precede B in the roadmap) are reporting and analysis exercises. B is the **first initiative in the roadmap where the deliverable is a working planning system** — a step up in ambition, but still bounded by well-understood techniques and the data Atlas already owns.

Scope boundary

In scope

- Weekly reorder recommendations for all active paint and hardware products
- Forecast window covers each supplier's lead time plus the weekly review cycle (typically 7–75 days depending on the product)
- Human sign-off: the GM / procurement lead reviews and approves recommendations before any PO is sent
- A weekly plain-language briefing that triages the week (act now / defer / consolidate by supplier) plus a "why" explanation for each recommendation
- Accuracy and stockout-days tracking dashboard for continuous improvement
- Runs on the existing Atlas server; no cloud dependency

Out of scope

- Automatic ordering from suppliers (manual PO placement continues)
- Multi-location balancing (the inventory in scope is single-location)
- Production scheduling (that's Phase 3, Use Case A; this initiative feeds it but doesn't solve it)
- Advanced AI forecasting models — queued for a later phase if the baseline underperforms on specific product segments

Justification

Pain is concrete and measurable. 2-month stockouts and deadstock accumulation were surfaced by the GM in the 1st-deliverable discovery. They translate directly into lost sales and tied-up working capital.

Data exists and is clean. 10+ years of sales, bills of material, purchase orders, and inventory snapshots are all in the ERP and readable by the system. Lead times are known per supplier.

Technique is mature and transparent. The underlying approach has been the inventory-planning standard since the 1950s. There is no black box, which matters for a company with no prior AI experience and no internal data team.

Pre-requisite (Phase 0) is already scheduled. Inventory-accuracy cycle counting and populating reorder points in the ERP is the named Phase 0 in the roadmap; this initiative consumes that output directly.

3. Business Problem & Value

Current state

- **Procurement is reactive.** The CEO places orders when sales reps, the GM, or the warehouse flag a shortage. There is no calendar for review and no forecast.
- **Lead times are long.** Hardware imports take 55–75 days from order to arrival, depending on the supplier. Lead times are stored in the ERP today but unevenly — Phase 0 includes standardising lead-time capture per supplier so the forecasting engine can rely on them.
- **Stockouts are expensive.** The primary revenue driver (hardware sales) stops the moment a key SKU runs out, and the next delivery is 2 months away. Atlas's B2B customers (retail shops, contractors) then buy from competitors.
- **Deadstock is invisible.** Slow-moving items stay on the shelves unobserved because nobody tracks coverage days.
- **Seasonal peaks are not planned for.** March and summer see ~1.8× baseline demand; Dec–Feb sees ~0.55×. Without planning, inventory arrives after the peak and sits through the trough.

Target state

- Every Monday, the GM and procurement lead open a local dashboard showing:
 - **Products to reorder this week** — ranked by stockout risk and order value
 - **Why** each product needs to be reordered (plain-language explanation)
 - **Suggested order quantity** and expected arrival date
 - **Drill-down charts** showing 10-year history and the forward forecast
- Procurement reviews, approves (or edits), and sends POs to suppliers.
- Exceptions and accuracy are reviewed monthly, and buffers are tuned per product segment.

Value framing

This initiative does two things simultaneously:

Avoids revenue loss from stockouts on the primary revenue category (hardware imports).

Releases working capital by not over-ordering on slow-movers.

The combined financial effect is typically the largest single P&L move a small wholesaler can make, and this is reflected in the 2nd-deliverable Business Impact score of **3.8/5**.

Why this works for Atlas specifically

- Atlas already has 10+ years of structured sales history — the single largest input an inventory model needs.
- Lead times are known per supplier.
- The GM makes procurement calls directly, so adoption does not require multi-layer change management.
- The organization is small enough (~16 employees) that a weekly review cadence is realistic from week one.

4. How the Solution Works

4.1 What the system reads from the ERP

The system only reads from Atlas's ERP — it never writes back. It uses:

- **Product catalogue** — SKUs, suppliers, costs, lead times
- **10+ years of daily sales history**
- **Current and historical on-hand inventory**
- **Open and past purchase orders**

No customer or personal data is used. No external data sources are required. Everything stays on Atlas's own server.

4.2 How it forecasts and decides what to reorder

For each product, the system learns its normal monthly rhythm from 10+ years of history, then projects demand across the supplier's lead time. It compares that projected demand to what's currently on hand plus anything already on order, and flags any product where the gap is too narrow to cover the wait.

A safety buffer — sized against how noisy each product's demand has been — protects against surprise spikes. Fast-moving stable products get a small buffer; lumpy, unpredictable products get a larger one.

The underlying approach is a mature, transparent technique used in inventory management since the 1950s. It is deliberately not machine learning: a business with no internal data team should be able to understand why the system recommends what it recommends. More sophisticated techniques are held in reserve for a later phase, only if specific product segments underperform.

4.3 The weekly briefing and plain-language explanations

The AI layer does two jobs, both on top of the same engine numbers:

A weekly procurement briefing. Rather than handing the GM a 13-row table to interpret, the system writes a short Monday-morning briefing that *triages the week* — which few orders genuinely need action today (and why, in terms of cover vs. lead time), which low-risk items can safely wait a cycle, and where several flagged products share a supplier and should be combined into one purchase order. If a weekly purchase budget is set and the recommendations exceed it, the briefing prioritises the high-risk items and says which to defer. This is judgement and synthesis a human planner would otherwise do by hand — not a restatement of a single row.

A per-product "why." Each individual recommendation in the drill-down is paired with a 2–3 sentence plain-language explanation of its reasoning.

Both are produced by an AI language model when the server is online, and by a built-in deterministic template when it is offline or unreachable — the same underlying numbers either way, with the dashboard labelling which path was used.

The model never invents figures, and this is enforced, not just instructed. Before any AI-written text is shown, an automated *grounding check* verifies that every number in it traces back to a value the reorder engine produced; if a figure cannot be traced, the AI output is rejected and the deterministic template is shown instead. The benefit (analysis and explanations a non-technical user can read) therefore never comes at the cost of a fabricated number or a dependency on internet connectivity — both realistic concerns given Atlas's infrastructure.

For algorithm detail, data schemas, and implementation specifics, see the accompanying Technical Overview.

5. Data Flow

The end-to-end flow is five steps, run on a weekly cadence:

Extract — a scheduled, read-only pull from the Atlas ERP refreshes a local cache.

Forecast — for each active product, demand is projected over the supplier's lead time, accounting for seasonality.

Recommend — the reorder engine compares forecast demand to what's on hand and on order, flags at-risk products, and suggests quantities.

Explain — the system writes a weekly briefing that triages the batch (act now / defer / consolidate by supplier, within any set budget) and a 2–3 sentence "why" for each flagged product.

Review & approve — GM and procurement open a local dashboard, review and approve (or edit) the recommendations, and send POs through the existing procurement channel.

Nothing writes back to the ERP automatically. Every PO remains a human decision. The only step that touches the internet is the optional AI explanation call — and if that's unavailable, the system uses a built-in template instead.

6. System Architecture

The entire system runs on Atlas's existing on-site server. There is no new hardware to buy, no cloud account to open, and no licence to renew.

- **Server-side:** a scheduled background process refreshes the local cache, runs the forecasting and reorder engine, and serves a dashboard to the office network.
- **User-side:** the GM and procurement access the dashboard through a normal web browser on the local network. No installation on their machines.
- **Internet:** only the optional AI explanation step leaves the network. If internet is down or disabled, the system falls back to a template and keeps running. The reorder recommendations themselves never depend on the internet.

This design is a deliberate match for Atlas's reality: unreliable internet, no cloud budget, and sensitivity around keeping ERP data on-site.

7. Implementation Plan & Timeline

Aligns with the 2nd deliverable's **Phase 2 (3–9 months)** slot in the roadmap. Timeline is compressed vs. the MedLinka reference because Atlas is a 16-person company with a direct decision-maker.

Sprint	Weeks	Scope	Owner	Output
S0 — Prerequisite	Week -4 to Week 0	Phase 0: inventory-accuracy cycle count; populate reorder points in ERP	GM + warehouse	Trusted on-hand figures, reorder point fields populated
S1 — Data extract	Week 1–2	Read-only extract from the ERP into a local cache; schedule weekly refresh	Consultant	Scheduled extract job, validated row counts
S2 — Forecasting v1	Week 3–4	Build the forecasting engine, validate on historical months, tune settings	Consultant	Forecast engine; accuracy backtest by product segment
S3 — Reorder engine	Week 5	Build the reorder logic, integrate with the forecast, compare to known stockout events	Consultant	Reorder engine; list of products the system would have flagged ahead of past stockouts
S4 — Dashboard and explanation layer	Week 6–7	Build the dashboard, drilldown, and what-if views; wire in the AI explanation with template fallback	Consultant	Usable app on the Atlas server
S5 — UAT with GM + procurement	Week 8–9	Parallel run: system makes recommendations, existing reactive process also runs, decisions compared	GM + procurement + consultant	Decision log showing the recommendations would have prevented N past stockouts and released \$X of deadstock
S6 — Go-live	Week 10	System becomes authoritative for reorder decisions; weekly review cadence starts	GM + procurement	Weekly PO batch based on system recommendations
S7 — Tune and hand over	Week 11–16	Tune buffers by product segment, add specialised techniques for lumpy-demand products if needed, build the monthly accuracy report	Consultant + GM	Tuned system; go / no-go decision on Phase 3

Total elapsed: ~4 months consultant engagement, with Phase 0 running in parallel starting immediately.

8. Risks & Mitigations

#	Risk	Likelihood	Impact	Mitigation
R1	Inventory accuracy is poor — on-hand in ERP $\neq$ reality, so reorder math produces wrong answers	High	Critical	Phase 0 cycle count is a hard prerequisite; go-live blocked until cycle count completes on hardware top-80%
R2	Forecasts are less accurate on low-volume hardware products with lumpy demand	Medium	Medium	Safety stock absorbs forecast error by design; specialised techniques for lumpy-demand products are queued for a later phase if needed
R3	Staff distrust the recommendations and revert to reactive ordering	Medium	High	2-week UAT parallel run creates evidence; plain-language "why" explanations help non-technical adoption; GM is the named owner
R4	Connectivity drops disable the AI explanations	High	Low	Template fallback runs fully offline with the same underlying numbers
R5	Single-server infrastructure fails	Low	High	The entire system fits on a USB stick; backup and runbook delivered with go-live
R6	Macro volatility (FX, imports) changes lead times suddenly	High	Medium	Lead-time buffer is a tunable setting; monthly review re-fits it; supplier-specific lead times stored per product

#	Risk	Likelihood	Impact	Mitigation
R7	The AI invents a number in an explanation	Low	Medium	Guardrails forbid new numbers; the template fallback is purely mechanical and cannot invent anything; the dashboard labels each explanation's source
R8	GM attention drops after 4–6 weeks	Medium	Medium	Weekly review tied to existing procurement cycle; stockout-avoided metric published monthly to keep the value visible
R9	Budget disappears mid-engagement	Medium	High	Phase 0 and S1–S4 are designed to be self-contained; if the engagement pauses after S3, the business still gets forecasts and reorder recommendations even without the dashboard

9. Governance, Privacy & Evaluation

Governance

- **Human-in-the-loop is mandatory.** The system *recommends*; a human *decides* and *places* POs. No automated supplier ordering in this initiative.
- **Explanation guardrails (enforced).** The AI layer is constrained to use only numbers the reorder engine produced. This is checked automatically: before any AI-written briefing or explanation is displayed, a grounding check confirms every figure in it traces to an engine value — if not, the output is rejected and the deterministic template is shown instead. The dashboard labels every output with its source so the reviewer knows whether they're reading AI-generated or template text.
- **Audit trail.** Every recommendation and decision is logged weekly (product, recommended quantity, approved quantity, approver, and reason if overridden).
- **Change control.** Any change to forecasting settings, buffer levels, or the explanation template is tracked; a monthly review assesses whether recent overrides signal that settings need tuning.

Privacy

- **No personal data.** Only product-level and supplier-level data is used. Customer data is not touched by this initiative.
- **Internal only.** All data stays on Atlas's server. The only traffic that ever leaves the network is the optional AI explanation call, and only product-level information is sent — never customer data.
- **AI layer is optional.** The system is fully functional without it. Atlas can turn it off and still get recommendations with template-based explanations.

Evaluation

Primary metrics, tracked weekly:

Metric	What it measures	Target (12 months post-launch)
Forecast accuracy (paint)	how close the monthly forecast is to actual sales	typical error $\leq$ 20%
Forecast accuracy (hardware)	same, for hardware (demand is lumpier so tolerance is wider; safety stock compensates)	typical error $\leq$ 50%
Stockout days avoided	days a top-20% product was below its reorder point over 12 months, year-over-year	-40%
Deadstock reduction	value of products sitting on shelves with more than 6 months of cover	-30%
Recommendation acceptance rate	share of recommendations approved as-is by the GM	$\geq$ 70% by month 3
PO placement lead time	days from weekly review to PO sent to supplier	$\leq$ 2 days

Secondary: service-level compliance per product segment; quarterly business review.

10. Budget & Resource Estimate

Cost profile

Atlas is explicitly a **zero-budget** engagement per the 1st-deliverable discovery. The solution is therefore designed so that the only hard cost is the consultant's time.

Category	Estimate	Notes
Consultant time (S0–S7)	~8–12 person-weeks over 4 months	single consultant; principal-level AI/data eng.
Software	\$0	Everything runs on an open-source stack — no licences required
AI explanation (optional)	< \$5 / month at Atlas volumes	Charged per explanation call. Entirely optional — the system works without it.
Infrastructure	\$0	Runs on Atlas's existing on-site server
Training	2 × half-day sessions	GM and procurement; covered in S5 UAT
Ongoing maintenance	~1 day / month	Buffer tuning, monthly accuracy review; can be delivered by the consultant on retainer or transferred to an internal champion

Internal resource commitments

- **GM:** ~2 hours / week during S5–S7; ~30 minutes / week steady state (weekly review).
- **Procurement:** ~2 hours / week steady state (weekly review + PO placement).
- **Warehouse lead:** sign-off on Phase 0 cycle count (one-time, ~1 week effort distributed).

11. Appendix — PoC Scoping Checklist & Assumptions

PoC Scoping Checklist

Item	Status	Notes
Target use case selected	■	Use Case B per 2nd-deliverable prioritisation
Data source identified	■	Atlas ERP; synthetic data for the PoC
Method specified	■	Demand forecast with seasonality + reorder-point logic with safety buffer
User interface specified	■	Local dashboard with three views: overview, product drilldown, what-if

Item	Status	Notes
AI boundary defined	■	Weekly briefing (triage / consolidation) + per-product explanations; bounded by an enforced numeric-grounding check, with an offline template fallback
Evaluation method	■	Accuracy backtest per product + recommendation acceptance rate
Governance posture	■	Human sign-off; audit log; AI guardrails
Infrastructure compatibility	■	Runs on Atlas's own server; office-network only; no cloud required
Out-of-scope items documented	■	Section 2
Demo script prepared	■	Walkthrough script included with the deliverables

Assumptions (explicit)

The ERP is read-accessible from the Atlas server.

10+ years of sales history in the ERP is representative of forward patterns. *Risk if macro conditions shift drastically — mitigated by the lead-time buffer and monthly tuning.*

Lead times per supplier are known and updated in the ERP when they change.

The GM and procurement lead will participate in the weekly review during UAT and steady state.

Automatic supplier integration is not in scope; PO placement continues through the existing manual channel.

The synthetic data in the PoC reflects the shape of the real ERP (seasonality, lead-time distribution, product mix). Real-data performance will be validated during S2.

PoC deliverables summary

- **Dashboard app** — a weekly AI briefing that triages the reorder batch, an overview of products to reorder, per-product drilldown with forecast chart, and what-if analysis
- **Forecasting and reorder engine** — the code behind the recommendations
- **Methodology notebook** — walkthrough of the approach with an accuracy backtest
- **This proposal + Technical Overview** (for the implementation team) + **5-minute demo walkthrough script**

All PoC code runs fully locally. The AI explanation layer is optional and degrades gracefully when offline — mirroring the Atlas production environment.
